Smaller capacity may include the reduction in capacity of one or more cells of the NAND flash memory, while larger capacity may include the reduction in capacity of one or more cells of the NAND flash memory, together with the addition of one or more extra cells. A cell of the NAND flash memory is a unit of storage of a memory of the NAND flash memory and it is composed of one or more transistors. FIG. 1 is a diagram of a structure of a conventional NAND flash memory. As shown in FIG. 1, in a memory cell array 100, a plurality of word lines 102 are arranged in a row direction, and a plurality of bit lines 104 are arranged in a column direction. Each of the word lines 102 and each of the bit lines 104 are formed to have a folded shape, for example, of a mushroom shape or a bar shape. Each of the word lines 102 is electrically connected to one end of a respective one of a plurality of MOS transistors (not shown) that compose a memory cell, and each of the bit lines 104 is electrically connected to one end of a respective one of a plurality of MOS transistors (not shown) that compose a memory cell. The MOS transistors are electrically isolated by an insulating film of ONO-type between the word lines 102 and the bit lines 104. The respective other end of each of the MOS transistors is connected to a respective one of a plurality of common source lines 106 arranged in the row direction. When the capacity of one or more cells of the NAND flash memory is reduced, the number of cells connected to each of the word lines 102 and each of the bit lines 104 is reduced, and the number of cells connected to each of the word lines 102 and each of the bit lines 104 is varied. Due to the variation in the number of cells connected to each of the word lines 102 and each of the bit lines 104, a voltage drop occurs. When such a voltage drop occurs, a difference in voltage between the word lines 102 and the bit lines 104 becomes large. In this way
